# R-package FME: inverse modelling, sensitivity, Monte Carlo - applied to a dynamic simulation model

Karline Soetaert NIOO-CEME The Netherlands

#### Abstract

Rpackage **FME** (Soetaert 2009a) contains functions for model calibration, sensitivity, identifiability, and Monte Carlo analysis of nonlinear models.

This vignette (vignette("FMEdyna")), applies the functions to a dynamic simulation model, solved with integration routines from package **deSolve** .

A similar vignette, (vignette("FMEsteady")), applies FME to a partial differential equation, solved with a steady-state solver from package rootSolve

A third vignette (vignette ("FMEother")), applies the functions to a simple nonlinear model

vignette("FMEmcmc") tests the Markov chain Monte Carlo (MCMC) implementation

Keywords: dynamic simulation models, differential equations, fitting, sensitivity, Monte Carlo, identifiability, R.

# 1. Introduction

R-package **FME** contains part of the functions present in the software environment FEMME (Soetaert, deClippele, and Herman 2002), a Flexible Environment for M athematically M odelling the Environment. FEMME was written in FORTRAN. **FME** is – obviously – written in

Although **FME** can work with many types of functions, it is mainly meant to be used with models that are written as (a system of) differential equations (ordinary or partial), which are solved either with routines from package deSolve (Soetaert, Petzoldt, and Setzer 2009), which integrate the model in time, or from package rootSolve (Soetaert 2009b) which estimate steady-state conditions. With **FME** it is possible to:

- perform local and global sensitivity analysis (Brun, Reichert, and Kunsch 2001; Soetaert and Herman 2009),
- perform parameter identifiability analysis (Brun et al. 2001),
- fit a model to data,
- run a Markov chain Monte Carlo (MCMC, Haario, Laine, Mira, and Saksman 2006).

Most of these functions have suitable methods for printing, visualising output etc. In addition, there are functions to generate parameter combinations corresponding to a certain distribution. In this document a – very quick – survey of the functionality is given, based on a simple model from (Soetaert and Herman 2009).

# 2. The example model

The example model describes growth of bacteria (BACT) on a substrate (SUB) in a closed vessel. The model equations are:

$$\frac{dBact}{dt} = gmax \cdot eff \cdot \frac{Sub}{Sub + ks} \cdot Bact - d \cdot Bact - r_B \cdot Bact$$

$$\frac{dSub}{dt} = -gmax \cdot \frac{Sub}{Sub + ks} \cdot Bact + d \cdot Bact$$

where the first, second and third term of the rate of change of Bact is growth of bacteria, death and respiration respectively. In R, this model is implemented and solved as follows (see help pages of **deSolve**). First the parameters are defined, as a list (a vector would also do)

```
> pars <- list(gmax =0.5,eff = 0.5,
+ ks =0.5, rB =0.01, dB =0.01)</pre>
```

The model function solveBact takes as input the parameters and the time sequence at which output is wanted. Within this function, derivs is defined, which is the *derivative* function, called at each time step by the solver. It takes as input the current time (t), the current values of the state variables (state) and the parameters (pars). It returns the rate of change of the state variables, packed as a list. Also within function solveBact, the state variables are given an initial condition (state) and the model is solved by integration, using function ode from package deSolve. The results of the integration are returned, packed as a data frame.

```
> solveBact <- function(pars, times=seq(0,50,by=0.5)) {
+ derivs <- function(t,state,pars) { # returns rate of change
+ with(as.list(c(state,pars)), {
+
+ dBact = gmax*eff*Sub/(Sub+ks)*Bact - dB*Bact - rB*Bact
+ dSub = -gmax *Sub/(Sub+ks)*Bact + dB*Bact
+ return(list(c(dBact,dSub)))
+ })
+ }
+ state <- c(Bact=0.1,Sub = 100)
+ ## ode solves the model by integration...
+ return(as.data.frame(ode(y=state,times=times,func=derivs,parms=pars)))
+ }</pre>
```

The model is then solved by calling solveBact with the default parameters:

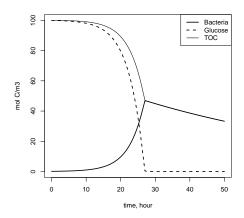

Figure 1: Solution of the simple bacterial growth model - see text for R-code

# 3. Global sensitivity

In global sensitivity analysis, certain parameters are changed over a large range, and the effect on certain model outur variables assessed. In **FME** this is done via function **sensRange**.

First the sensitivity parameters are defined and a distribution is assigned; here we specify the minimum and maximum values of three parameters in a data.frame:

```
> parRanges <- data.frame(min=c(0.4,0.4,0.0),max=c(0.6,0.6,0.02))
> rownames(parRanges)<- c("gmax","eff","rB")
> parRanges

    min max
gmax 0.4 0.60
eff 0.4 0.60
rB 0.0 0.02
```

Then we estimate the sensitivity to one parameter, rB (parameter 3), varying its values according to a regular grid (dist=grid). The effect of that on sensitivity variables Bact and Sub are estimated. To do this, the model is run 100 times (num=100). The system.time is printed (in seconds):

```
> tout
          <- 0:50
> print(system.time(
+ sR<-sensRange(func=solveBact,parms=pars,dist="grid",
                  sensvar=c("Bact", "Sub"), parRange=parRanges[3,], num=50)
+ ))
         system elapsed
   user
   1.44
           0.00
                   1.44
> head(summary(sR))
                 Mean
                                 Sd
                                          Min
                                                    Max
                                                               q05
                                                                         q25

Bact2
Bact2.5 0.1771627 0.1793911 0.1811941
```

The results are represented as a data frame, containing summary information of the value of the sensitivity variable (var) at each time step (x). It is relatively simple to plot the ranges, either as  $\min \pm sd$  or using quantiles:

```
> par(mfrow=c(2,2))
> plot(summary(sR),xlab="time, hour",ylab="molC/m3",
+ legpos="topright")
> plot(summary(sR),xlab="time, hour",ylab="molC/m3",
+ quant=TRUE,col=c("lightblue","darkblue"),legpos="topright")
> mtext(outer=TRUE,line=-1.5,side=3,"Sensitivity to rB",cex=1.25)
> par(mfrow=c(1,1))
```

Sensitivity ranges can also be estimated for a combination of parameters. Here we use all 3 parameters, and select the latin hypercube sampling algorithm.

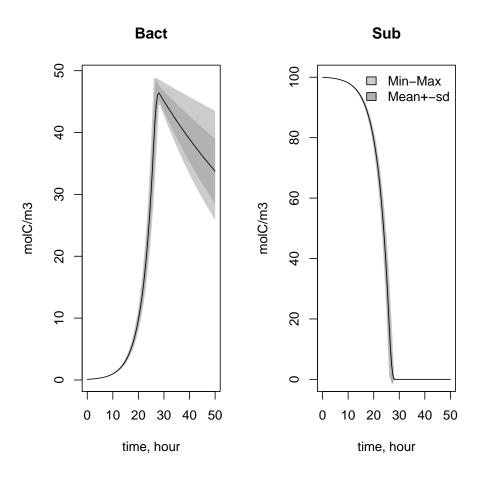

Figure 2: Sensitivity range for one parameter - see text for  $\mathsf{R}\text{-}\mathsf{code}$ 

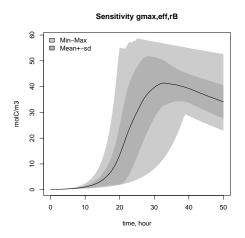

Figure 3: Sensitivity range for a combination of parameters - see text for R-code

# 4. Local sensitivity

In local sensitivity, the effect of a parameter value in a very small region near its nominal value is estimated. The methods implemented in **FME** are based on Brun *et al.* (2001) which should be consulted for details. They are based on so-called "sensitivity functions".

# 4.1. Sensitivity functions

> SnsBact <- sensFun(func=solveBact,parms=pars,

Sensitivity functions are generated with sensFun, and estimate the effect of a selection of parameters (here all parameters are selected) on a selection of variables (here only Bact).

```
sensvar="Bact", varscale=1)
> head(SnsBact)
                             eff
                                            ks
                                                                       dB
   x var
                 gmax
                                                         rB
1 0.0 Bact 0.00000000 0.00000000 0.0000000000
                                               0.000000000
                                                             0.000000000
2 0.5 Bact 0.01394713 0.01394714 -0.0000703354 -0.000560559 -0.0005605588
3 1.0 Bact 0.03127214 0.03127218 -0.0001562084 -0.001257071 -0.0012570697
4 1.5 Bact 0.05259210 0.05259221 -0.0002623735 -0.002114135 -0.0021141330
5 2.0 Bact 0.07861787 0.07861810 -0.0003921211 -0.003160362 -0.0031603571
6 2.5 Bact 0.11017714 0.11017756 -0.0005495271 -0.004429033 -0.0044290250
```

They can easily be plotted (Fig. 3):

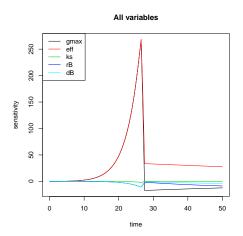

Figure 4: Sensitivity functions - see text for R-code

# > plot(SnsBact)

# 4.2. Univariate sensitivity

Based on the sensitivity functions, several summaries are generated, which allow to rank the parameters based on their influence on the selected variables.

## > summary(SnsBact)

	value	scale	L1	L2	Mean	Min	Max	N
gmax	0.50	0.50	29.51	5.859	16.2	-17.1	266.361	101
eff	0.50	0.50	37.12	6.212	37.1	0.0	268.408	101
ks	0.50	0.50	0.17	0.037	-0.1	-1.8	0.097	101
rB	0.01	0.01	3.47	0.463	-3.5	-10.8	0.000	101
dB	0.01	0.01	2.06	0.297	-2.1	-10.8	0.000	101

Here

- L1 is the L1-norm,  $\sum |S_{ij}|/n$
- L2 is the L2-norm,  $\sqrt{\sum (S_{ij}^2)/n}$
- Mean: the mean of the sensitivity functions
- Min: the minimal value of the sensitivity functions
- Max: the maximal value of the sensitivity functions

Sensitivity analysis can also be performed on several variables:

## > summary(sensFun(solveBact,pars,varscale=1),var=TRUE)

```
L2
      value scale
                     L1
                                 Mean
                                           Min
                                                   Max

> pairs(SnsBact)

#### 4.4. Monte Carlo runs

Function modCRL runs a Monte Carlo simulation, outputting single variables.

This is in contrast to sensRange which outputs vectors of variables, e.g. a time-sequence, or a spatially-dependent variable.

It can be used to test what-if scenarios. Here it is used to calculate the final concentration of bacteria and substrate as a function of the maximal growth rate.

```
> SF <- function (pars) {
+   out <- solveBact(pars)
+   return(out[nrow(out),2:3])
+ }
> CRL <- modCRL(func=SF,parms=pars,parRange=parRanges[1,])
> plot(CRL)
```

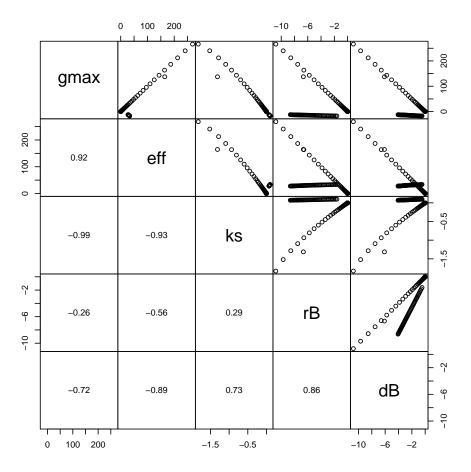

Figure 5: Pairs of sensitivity functions - see text for R-code

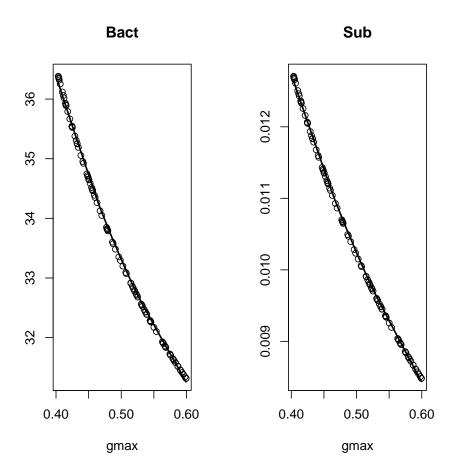

Figure 6: Monte carlo analysis - see text for  $\mathsf{R}\text{-}\mathsf{code}$ 

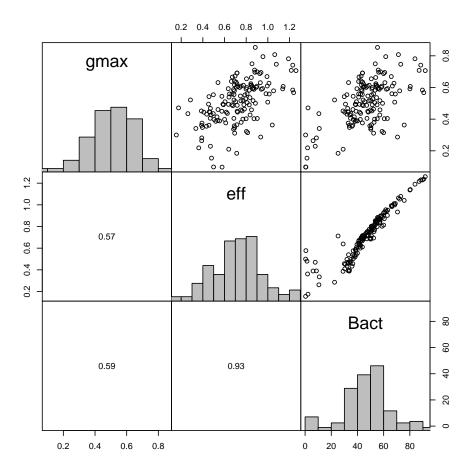

Figure 7: Multivariate Monte Carlo analysis - see text for R-code

Monte Carlo methods can also be used to see how parameter uncertainties propagate, i.e. to derive the distribution of output variables as a function of parameter distribution.

Here the effect of the parameters gmax and eff on final bacterial concentration is assessed. The parameter values are generated according to a multi-normal distribution; they are positively correlated (with a correlation = 0.63).

# 5. Multivariate sensitivity analysis

Based on the sensitivity functions of model variables to selection of parameters, function collin calculates the *collinearity* or *identifiability* of sets of parameters.

```
> Coll <- collin(SnsBact)
> Coll
```

	${\tt gmax}$	eff	ks	rB	dΒ	N	collinearity
1	1	1	0	0	0	2	2.8
2	1	0	1	0	0	2	9.5
3	1	0	0	1	0	2	1.3
4	1	0	0	0	1	2	1.8
5	0	1	1	0	0	2	2.9
6	0	1	0	1	0	2	2.0
7	0	1	0	0	1	2	3.7
8	0	0	1	1	0	2	1.3
9	0	0	1	0	1	2	1.8
10	0	0	0	1	1	2	3.8
11	1	1	1	0	0	3	9.5
12	1	1	0	1	0	3	7.0
13	1	1	0	0	1	3	6.8
14	1	0	1	1	0	3	9.5
15	1	0	1	0	1	3	9.5
16	1	0	0	1	1	3	2261.4
17	0	1	1	1	0	3	6.7
18	0	1	1	0	1	3	6.8
19	0	1	0	1	1	3	12.2
20	0	0	1	1	1	3	22.6
21	1	1	1	1	0	4	9.6
22	1	1	1	0	1	4	9.5
23	1	1	0	1	1	4	3631.3
24	1	0	1	1	1	4	3451.1
25	0	1	1	1	1	4	23.5
26	1	1	1	1	1	5	2421318.6

> Coll [Coll[,"collinearity"]<20&Coll[,"N"]==4,]</pre>

> collin(SnsBact,parset=1:5)

The higher the value, the larger the (approximate) linear dependence. This function is mainly useful to derive suitable parameter sets that can be calibrated based on data (see next section).

# 6. Fitting the model to data

#### 6.1. Data structures

There are two modes of data input:

- data table (long) format; this is a two to four column data.frame that contains the name of the observed variable (always the FIRST column), the (optional) value of the independent variable (default = "time"), the value of the observation and the (optional) value of the error.
- crosstable format; this is a matrix, where each column denotes one dependent (or independent) variable; the column name is the name of the observed variable.

As an example of both formats consider the data, called Dat consisting of two observed variables, called "Obs1" and "Obs2", both containing two observations, at time 1 and 2:

name	$_{ m time}$	val	$\operatorname{err}$
Obs1	1	50	5
Obs1	2	150	15
Obs2	1	1	0.1
Obs2	2	2	0.2

for the long format and

$_{ m time}$	Obs1	Obs2
1	50	1
2	150	2

for the crosstable format. Note, that in the latter case it is not possible to provide separate errors per data point.

# 6.2. The model cost function

**FME** function modCost estimates the "model cost", which the sum of (weighted) squared residuals of the model versus the data. This function is central to parameter identifiability analysis, model fitting or running a Markov chain Monte Carlo.

Assume the following model output (in a matrix or data.frame called Mod:

$_{ m time}$	Obs1	Obs2
0	4	1
1	4	2
2	4	3
3	4	4

Then the modCost will give:

```
> Dat<- data.frame(name=c("Obs1","Obs1","Obs2","Obs2"),

## 6.3. Model fitting

Assume the following data set (in crosstable (wide) format):

```
> Data <- matrix (nc=2,byrow=2,data=
+ c(2, 0.14,
                   4, 0.21,
                                6, 0.31,
                                              8,
                                                  0.40,
                                14, 1.42,
     10, 0.69,
                  12, 0.97,
                                             16,
                                                  2.0,
                                22, 6.5,
     18, 3.0,
                  20, 4.5,
                                             24,
                                                  9.5,
     26, 13.5,
                  28, 20.5,
                               30, 29, 35, 65, 40, 61)
+ )
> colnames(Data) <- c("time", "Bact")</pre>
> head(Data)
     time Bact
[1,]
        2 0.14
[2,]
        4 0.21
[3,]
        6 0.31
[4,]
       8 0.40
[5,]
      10 0.69
[6,]
       12 0.97
```

and assume that we want to fit the model parameters gmax and eff to these data.

We first define an objective function that returns the residuals of the model versus the data, as estimated by modcost. Input to the function are the current values of the parameters that need to be finetuned and their names (or position in par).

```
> Objective <- function(x,parset=names(x)) {
+ pars[parset] <- x
+ tout <- seq(0,50,by=0.5)
+ ## output times
+ out <- solveBact(pars,tout)
+ ## Model cost
+ return(modCost(obs=Data,model=out))
+ }</pre>
```

First it is instructive to establish which parameters can be identified based on the data set. We assess that by means of the identifiability function collin, selecting only the output variables at the instances when there is an observation.

```
> Coll <- collin(sF<-sensFun(func=Objective,parms=pars,varscale=1))
> Coll
```

	gmax	eff	ks	rB	dΒ	N	collinearity
1	1	1	0	0	0	2	4.5
2	1	0	1	0	0	2	21.1
3	1	0	0	1	0	2	2.1
4	1	0	0	0	1	2	3.7
5	0	1	1	0	0	2	4.5
6	0	1	0	1	0	2	3.3
7	0	1	0	0	1	2	9.2
8	0	0	1	1	0	2	2.1
9	0	0	1	0	1	2	3.7
10	0	0	0	1	1	2	4.5
11	1	1	1	0	0	3	21.1
12	1	1	0	1	0	3	10.2
13	1	1	0	0	1	3	10.5
14	1	0	1	1	0	3	21.1
15	1	0	1	0	1	3	21.1
16	1	0	0	1	1	3	3442.4
17	0	1	1	1	0	3	9.9
18	0	1	1	0	1	3	10.5
19	0	1	0	1	1	3	13.8
20	0	0	1	1	1	3	39.2
21	1	1	1	1	0	4	21.3
22	1	1	1	0	1	4	21.1
23	1	1	0	1	1	4	6465.5
24	1	0	1	1	1	4	4198.5
25	0	1	1	1	1	4	40.1
26	1	1	1	1	1	5	16346953.1

The larger the collinearity value, the less identifiable the parameter based on the data. In general a collinearity value less than about 20 is "identifiable". Below we plot the collinarity as a function of the number of parameters selected. We add a line at the height of 20, the critical value:

```
> plot(Coll,log="y")
> abline(h=20,col="red")
```

The collinearity index for parameters gmax and eff is small enough to enable estimating both parameters.

```
> collin(sF,parset=1:2)

gmax eff ks rB dB N collinearity
1  1  1  0  0  0  2     4.5
```

We now use function modFit to locate the minimum. It includes several fitting procedures; the default one is the Levenberg-Marquardt algorithm.

In the following example, parameters are constrained to be > 0

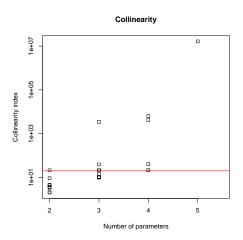

Figure 8: Collinearity analysis - see text for R-code

```
> print(system.time(Fit <- modFit(p=c(gmax=0.5,eff=0.5),</pre>
                    f=Objective,lower=c(0.0, 0.0)))
   user
         system elapsed
           0.01
                   0.99
   0.91

# 7. Markov chain Monte Carlo

We can use the results of the fit to run a MCMC (Gelman, Varlin, Stern, and Rubin 2004). Function modMCMC implements the delayed rejection (DR) adaptive Metropolis (AM) algorithm (Haario *et al.* 2006).

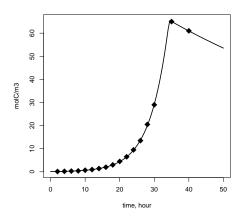

Figure 9: Fitting the model to data - see text for  $\mathsf{R}\text{-}\mathsf{code}$ 

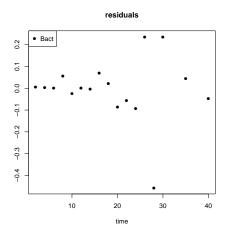

Figure 10: Model-data residuals - see text for  ${\sf R-code}$ 

The summary method of the best fit returns several useful values:

- the model variance modVariance is used as the initial model error variance (var0). In each MCMC step, 1/model variance is drawn from a gamma function with parameters shape=0.5\*N\*(1+pvar0), and the rate=0.5\*(pvar0\*N\*var0+SSnew)) and where SS is the current sum of squared residals, N is the number of data points and pVar0 is a weighing parameter, input to modMCMC.
- The best-fit parameters are used as initial parameter values for the MCMC (p).
- The parameter covariance returned by the summary method, scaled with  $2.4^2/length(p)$ , gives a suitable covariance matrix, for generating new parameter values (jump).

> MCMC<-modMCMC(p=coef(Fit),f=Objective,jump=covIni,
                var0=Var0, wvar0=1)
number of accepted runs: 350 out of 1000 (35%)
The plot method shows the trace of the parameters and, in Full is TRUE, also the model
function.
```

The pairs method plots both parameters as a function of one another:

> plot(MCMC,Full=TRUE)

> pairs(MCMC)

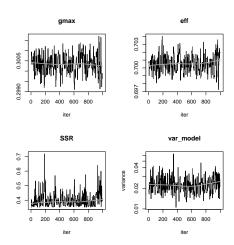

Figure 11: MCMC parameter values per iteration - see text for R-code

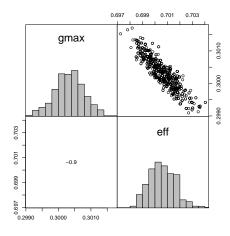

Figure 12: Pairs plot of MCMC results. See text for R-code

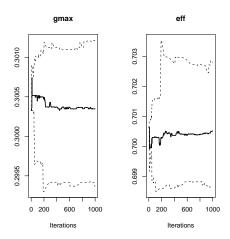

Figure 13: cumulative quantile plot from the MCMC run as from package  $\mathbf{coda}$  - see text for R-code

The MCMC output can be used in the functions from the **coda** package:

```
> MC <- as.mcmc(MCMC$pars)</pre>
```

> cumuplot(MC)

Finally, we compare the covariances based on generated parameters with the ones from the fit:

> cov(MCMC\$pars)

```

```

> covIni

# 8. Distributions

Parameter values can be generated according to 4 different distributions: Grid, Uniform, Normal, Latinhyper:

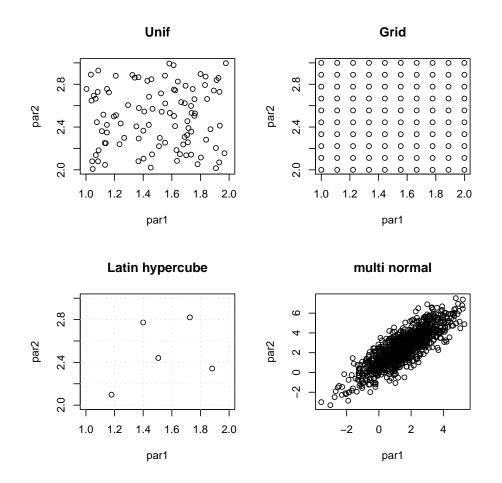

Figure 14: distributions

# 9. Examples

Several examples are present in subdirectory examples of the package. They include, a.o.:

• BODO2\_FME.R, a 1-D model of oxygen dynamics in a river. This model consists of

two coupled partial differential equations, which are solved to steady-state.

- ccl4model\_FME.R. Here the functions are applied to "ccl4model", one of the models included in package **deSolve**. This is a model that has been written in FORTRAN.
- Omexdia\_FME.R. Here the functions are applied to a model implemented in **simecol**, an object-oriented framework for ecological modeling (Petzoldt and Rinke 2007), more specifically in package **simecolModels** (Petzoldt and Soetaert 2008). The omexdia model is a 1-D diagenetic model.
- O2profile\_FME.R. This contains a simple model of oxygen, diffusing along a spatial gradient, with imposed upper and lower boundary concentration

# 10. Finally

This vignette is made with Sweave (Leisch 2002).

Table 1: Summary of the functions in package FME

Function	Description
sensFun	Sensitivity functions
sensRange	Sensitivity ranges
$\operatorname{modCost}$	Estimates cost functions
modFit	Fits a model to data
$\operatorname{modMCMC}$	Runs a Markov chain Monte Carlo
collin	Estimates collinearity based on sensitivity functions
Grid, Norm,	
Unif, Latinhyper	Generates parameter sets based on grid, normal, uniform or latin
	hypercube design

Table 2: Summary of the methods in package FME

Method	Function	Description
summary	$\operatorname{modFit}$	Summary statistics, including parameter std deviations, sig-
		nificance, parameter correlation
deviance	$\operatorname{modFit}$	model deviance (sum of squared residuals)
coef	modFit	values of fitted parameters
residuals	modFit	residuals of model and data
df.residual	modFit	degrees of freedom
print.summary	modFit	printout of model summary
summary	$\operatorname{modMCMC}$	Summary statistics of sampled parameters
plot	$\operatorname{modMCMC}$	Plots all sampled parameters
pairs	$\operatorname{modMCMC}$	Pairwise plots all sampled parameters
